

NEW ABSTRACT

An internet receiving arrangement, such as an internet radio, is connected to the internet and stores internet addresses of information servers which provide information data. The internet receiving arrangement has a quality test device for testing whether the received information data have a satisfactory quality. If the quality value of the received information data detected by the quality detector is below a quality threshold value, then the internet addresses stored in the internet receiving arrangement are updated with internet addresses of the information servers which are stored in an address server connected to the internet.
